

# Lecture 12: Brown Dwarf Multiplicity

# Definitions

Trapezium  
(visual multiple)

Mizar & Alcor (optical binary)

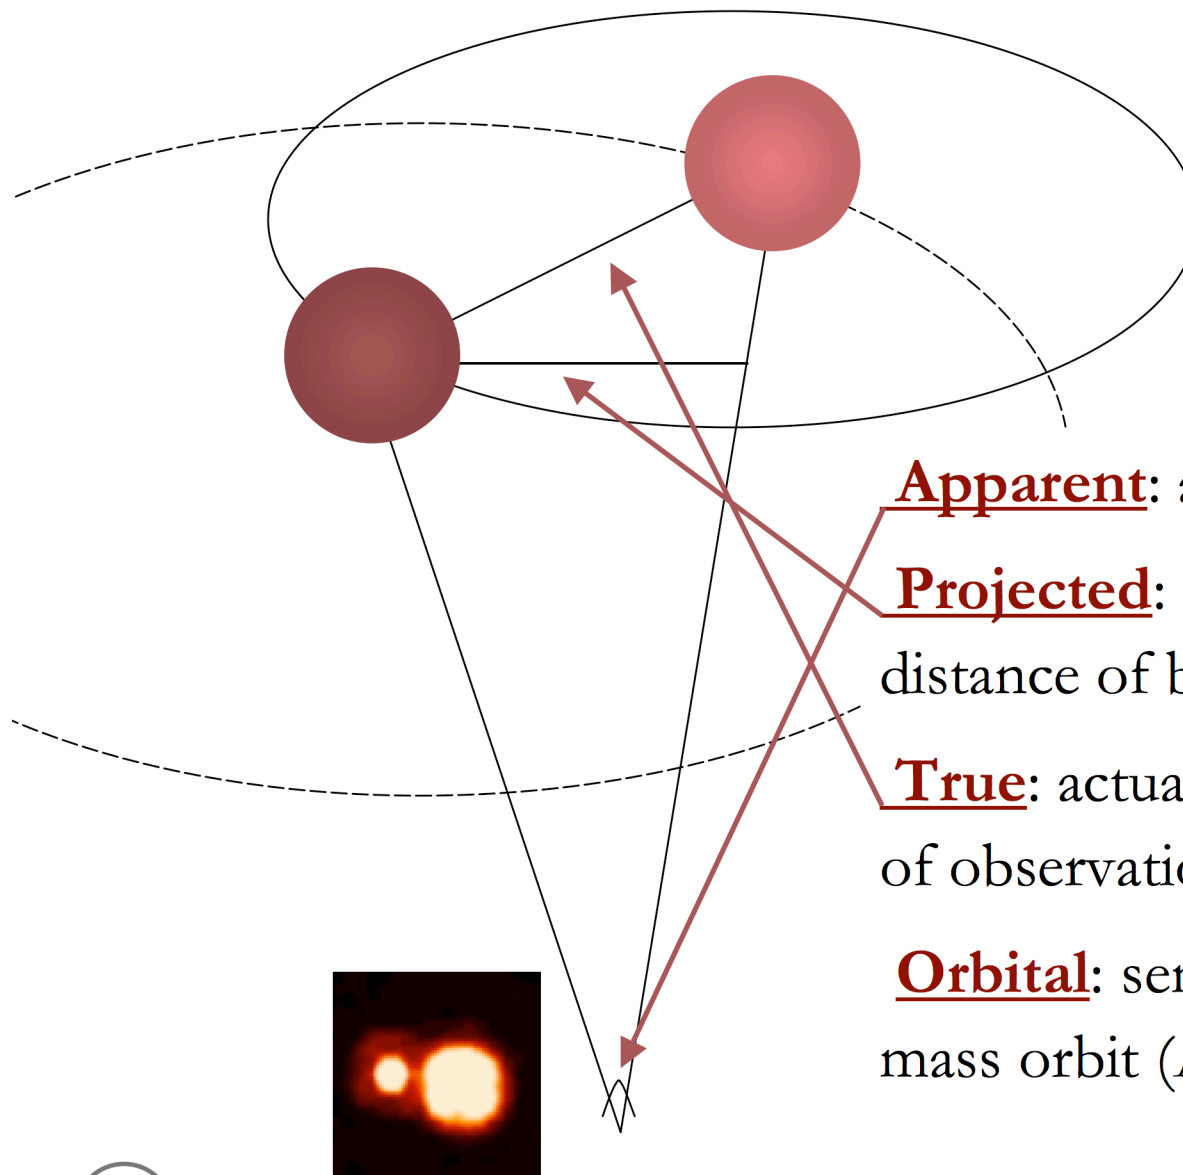

**Multiple/Double Stars:** a group of stars close to each other

**Visual binary:** gravitationally bound system

**Optical binary:** not bound

# Separations

**Apparent**: angular separation on sky ( $''$ )

**Projected**: separation in plane of sky at distance of binary (AU)

**True**: actual physical separation at time of observations (AU)

**Orbital**: semimajor axis of center-of-mass orbit (AU)

# Flux and Mass Ratios

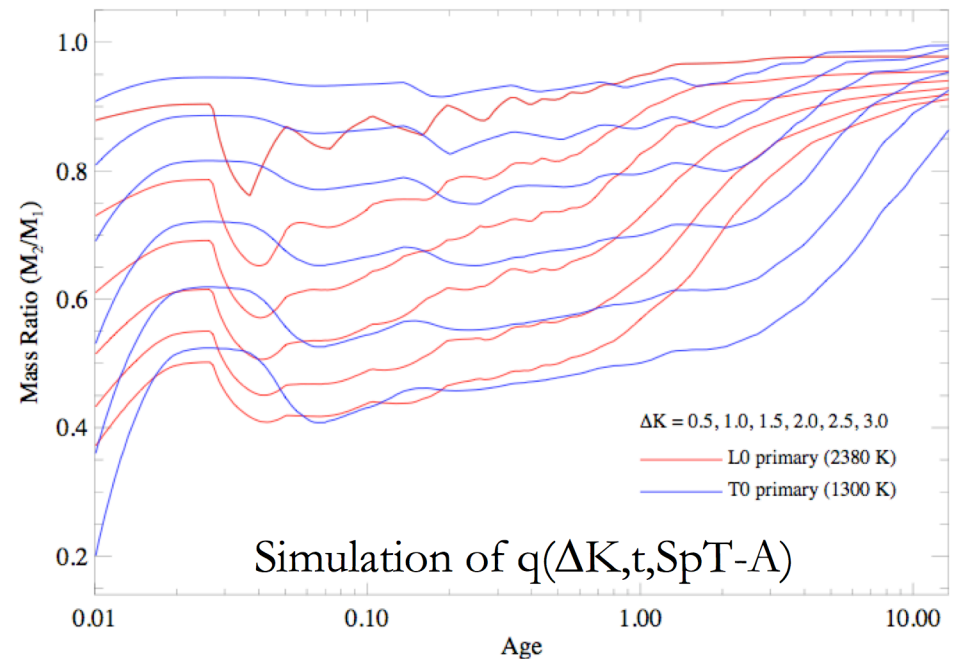

2MASS 1225-2739AB,  $\Delta\text{mag} = 1.6$

**Flux ratio:** relative brightness

**Mass ratio ( $q$ ):** relative mass ( $M_2/M_1 \leq 1$ )

## Caveat emptor!

Changing absorption features, H-burning boundary and age/mass degeneracy makes a 1-1 mapping between flux and mass ratios uncertain.

# Learn Your Fractions

**Multiplicity fraction** = fraction of systems that are multiple

$$\epsilon_M = (N_{\text{bin}} + N_{\text{trip}} + N_{\text{quad}} + \dots) / N_{\text{sys}}$$

$$\epsilon_M \approx \epsilon_B = N_{\text{bin}} / N_{\text{sys}}$$

**Single star fraction** = probability that a given star is single

$$f_s = N_{\text{sing}} / N_{\text{total}} = 1 - (2N_{\text{bin}} + 3N_{\text{trip}} + 4N_{\text{quad}} + \dots) / N_{\text{total}}$$

$$N_{\text{total}} = N_{\text{sing}} + 2N_{\text{bin}} + 3N_{\text{trip}} + 4N_{\text{quad}} + \dots$$

# Distributions

**Mass ratio distribution =  $f(q)$**

= frequency of binaries as  
function of  $M_2/M_1$

**Separation distribution =  $f(a)$**

= frequency of binaries as a  
function of (projected)  
separation - also shown as a  
period distribution

# Observational Methods

## Imaging

**\*Direct imaging**, eclipses (transits), overluminous (clusters), astrometric wobble, microlensing;

Advanced methods: adaptive optics, coronagraphy, spectral difference imaging, combinations of the above!

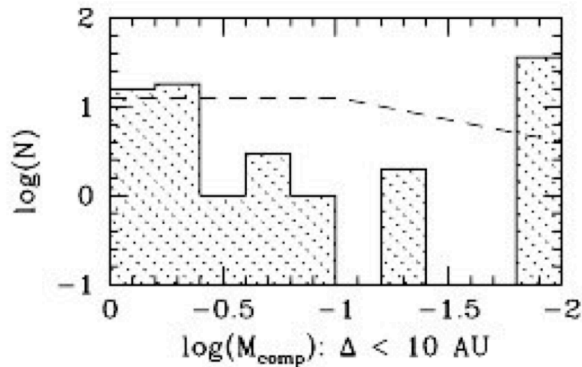

## Spectroscopy

Radial velocity variability (SB1 & SB2); spectral synthesis modeling (new!)

# Stellar Multiplicity

**F-K dwarfs,  $d < 25$  pc**

- Multiplicity fraction decreases with mass
  - A-B stars ~ **80%** (Shatsky and Tokovinin 2002; Kouwenhoven et al. 2005)
  - G dwarfs ~ **65%** (Duquennoy & Mayor 1991)
  - M dwarfs
    - ~ **42%** (Fischer & Marcy 1992)
    - ~ **27%** (Reid & Gizis 1997, Delfosse et al. 2004)
- **for volume limited samples**
- Separation distribution is broad (0.1 AU - 0.1 pc), peaks ~ 30 AU (G-M dwarfs)
- Mass ratio ( $q$ ) distribution is flat-ish (separation-dependent), companions apparently drawn from same IMF

---

Abt & Levy (1967); Abt (1987); Henry & McCarthy (1990); Duquennoy & Mayor (1991); Fischer & Marcy (1992); Mayor et al. (1992); Mazeh et al. (1992,1996,2003); Reid & Gizis (1997); Delfosse et al. (2004)

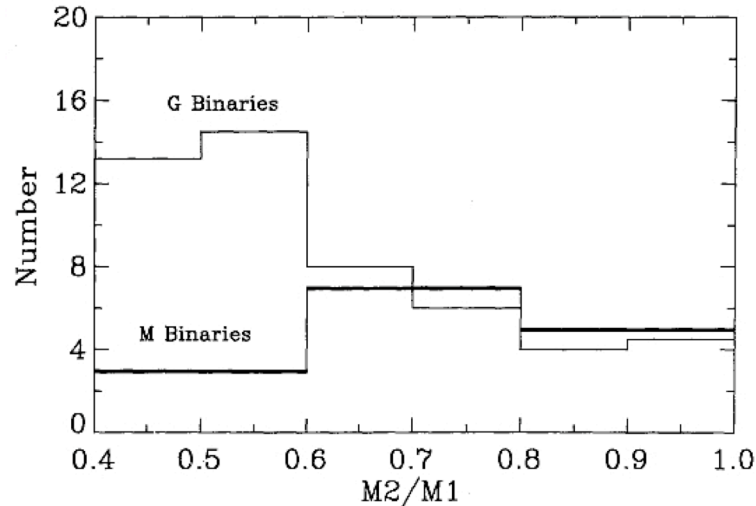

# Stellar Binaries

G and M dwarfs have:

- Similar period distributions
- Somewhat different mass ratio distributions - but both consistent with random assignment from IMF

Indicative of common formation mechanisms

Fischer & Marcy (1992)

# Known VLM Multiples

As of April 2007:

**85 multiples with  $M_1 \leq 0.1 M_\odot$**

**38** have  $M_1 \leq 0.072 M_\odot$

**78** identified via direct imaging

**7** identified via RV variability

**1** identified as an eclipsing system (2MASS 0535-0546; Stassun et al. 2006)

**10** are companions to more massive primaries

**4** are possible higher order VLM systems

**67** are systems in the field

**11** are members of young ( $< 10$  Myr) clusters/associations

2MASS 1207-3932AB  
Chauvin et al. (2004)

See [http://paperclip.as.arizona.edu/~nsiegler/VLM\\_binaries/](http://paperclip.as.arizona.edu/~nsiegler/VLM_binaries/)

# General Properties of VLM Binaries

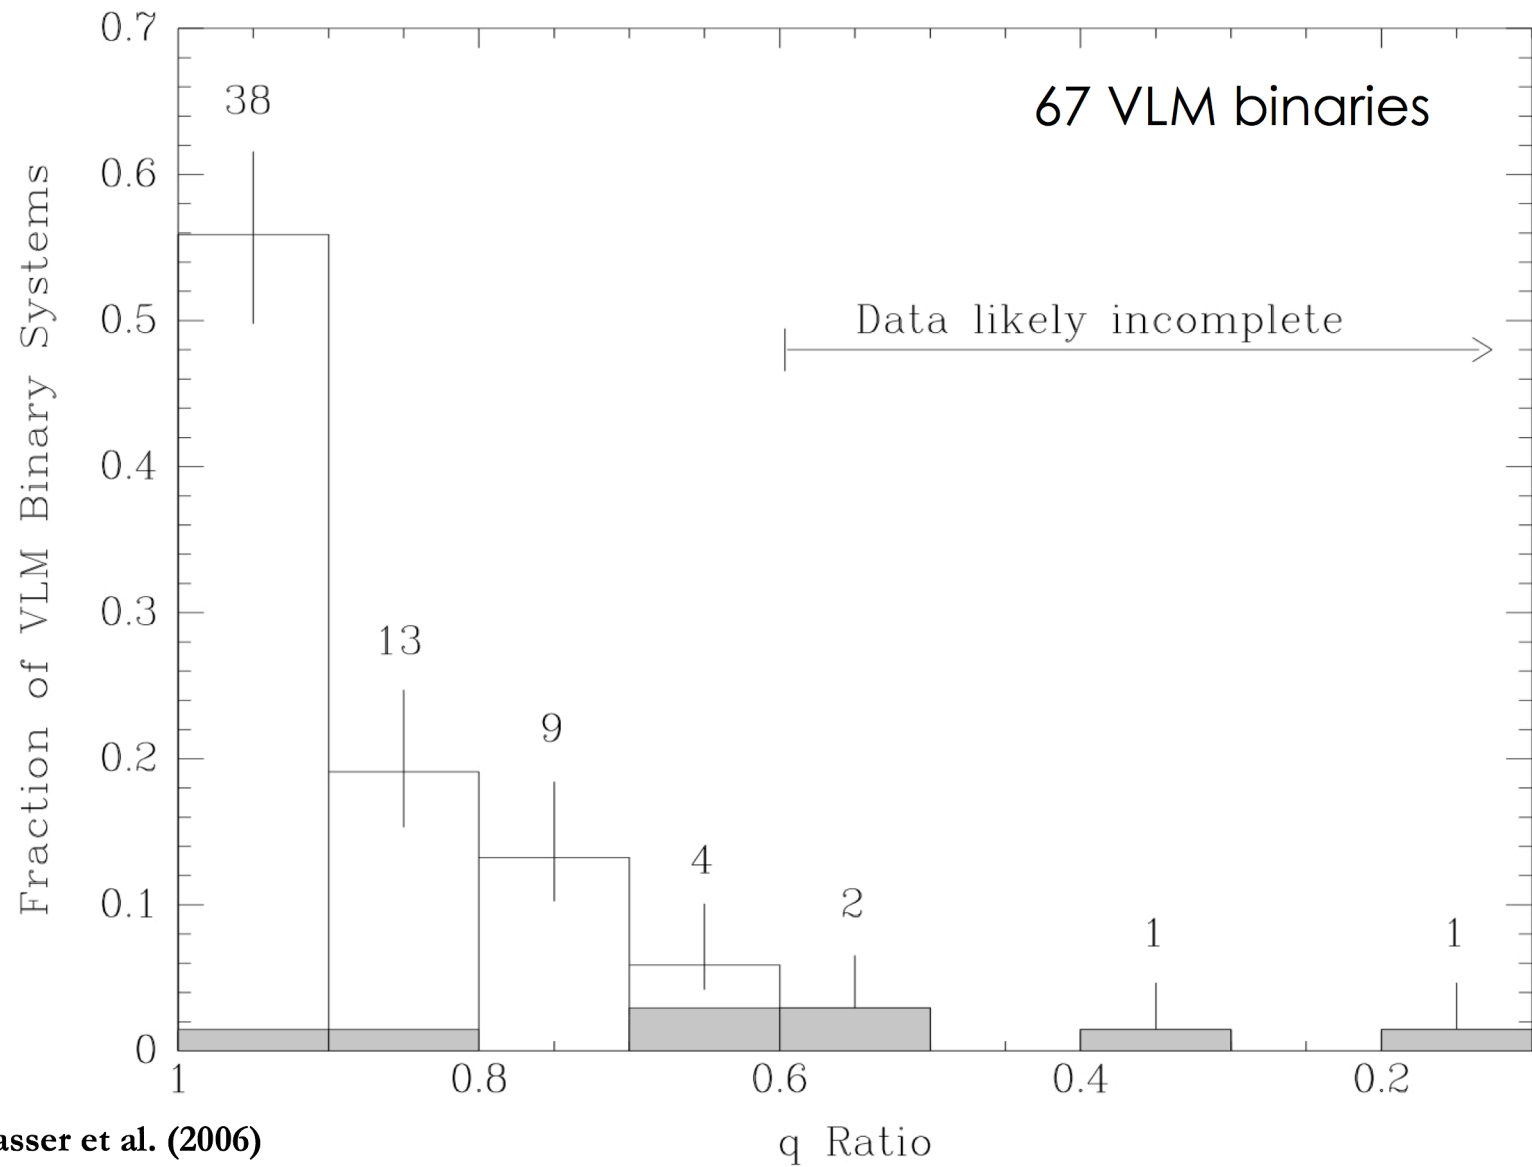

(Burgasser et al. 2007 PPV Chapter, and references therein)

1. Relatively rare ( $\epsilon_B = 10\text{-}20\%$ )  
\*different from stellar binaries!
2. Mostly “tight” systems (89% have  $a < 20$  AU)  
\*different from stellar binaries!
3. Mostly equal-mass systems (76% have  $q \geq 0.8$ )  
\*different from stellar binaries!

**Do differences indicate brown dwarfs form differently than stars?**

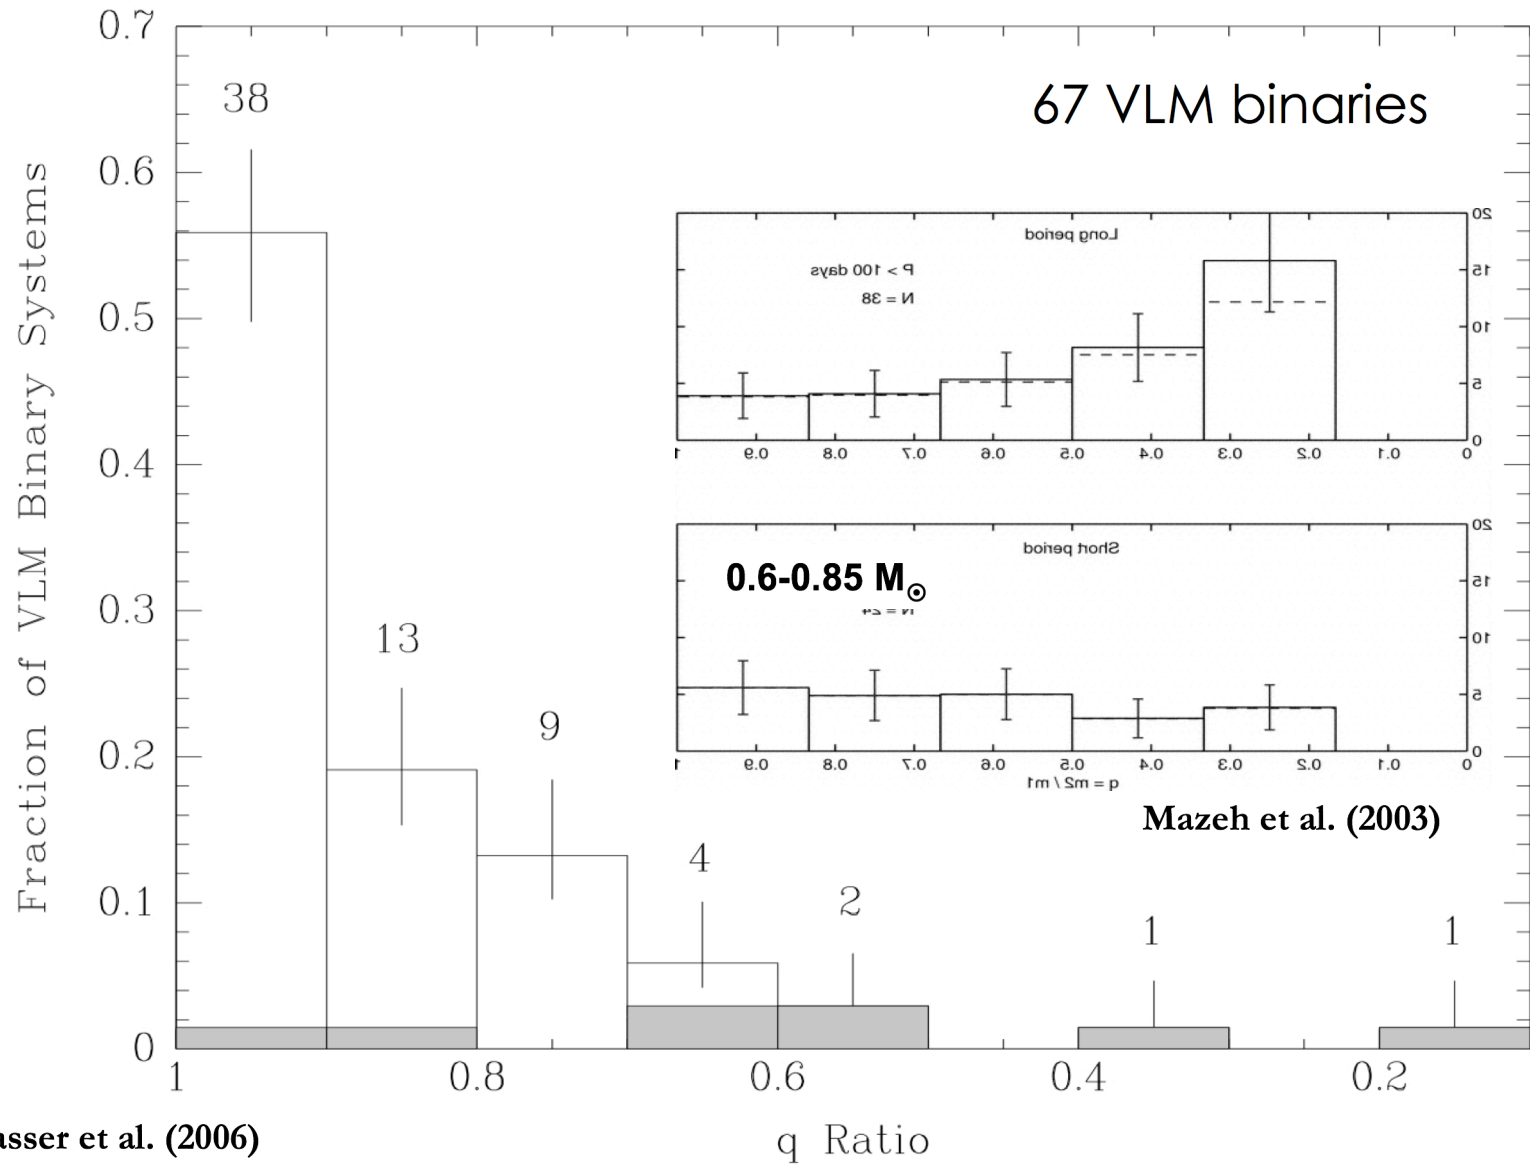

# Mass Ratio Distribution

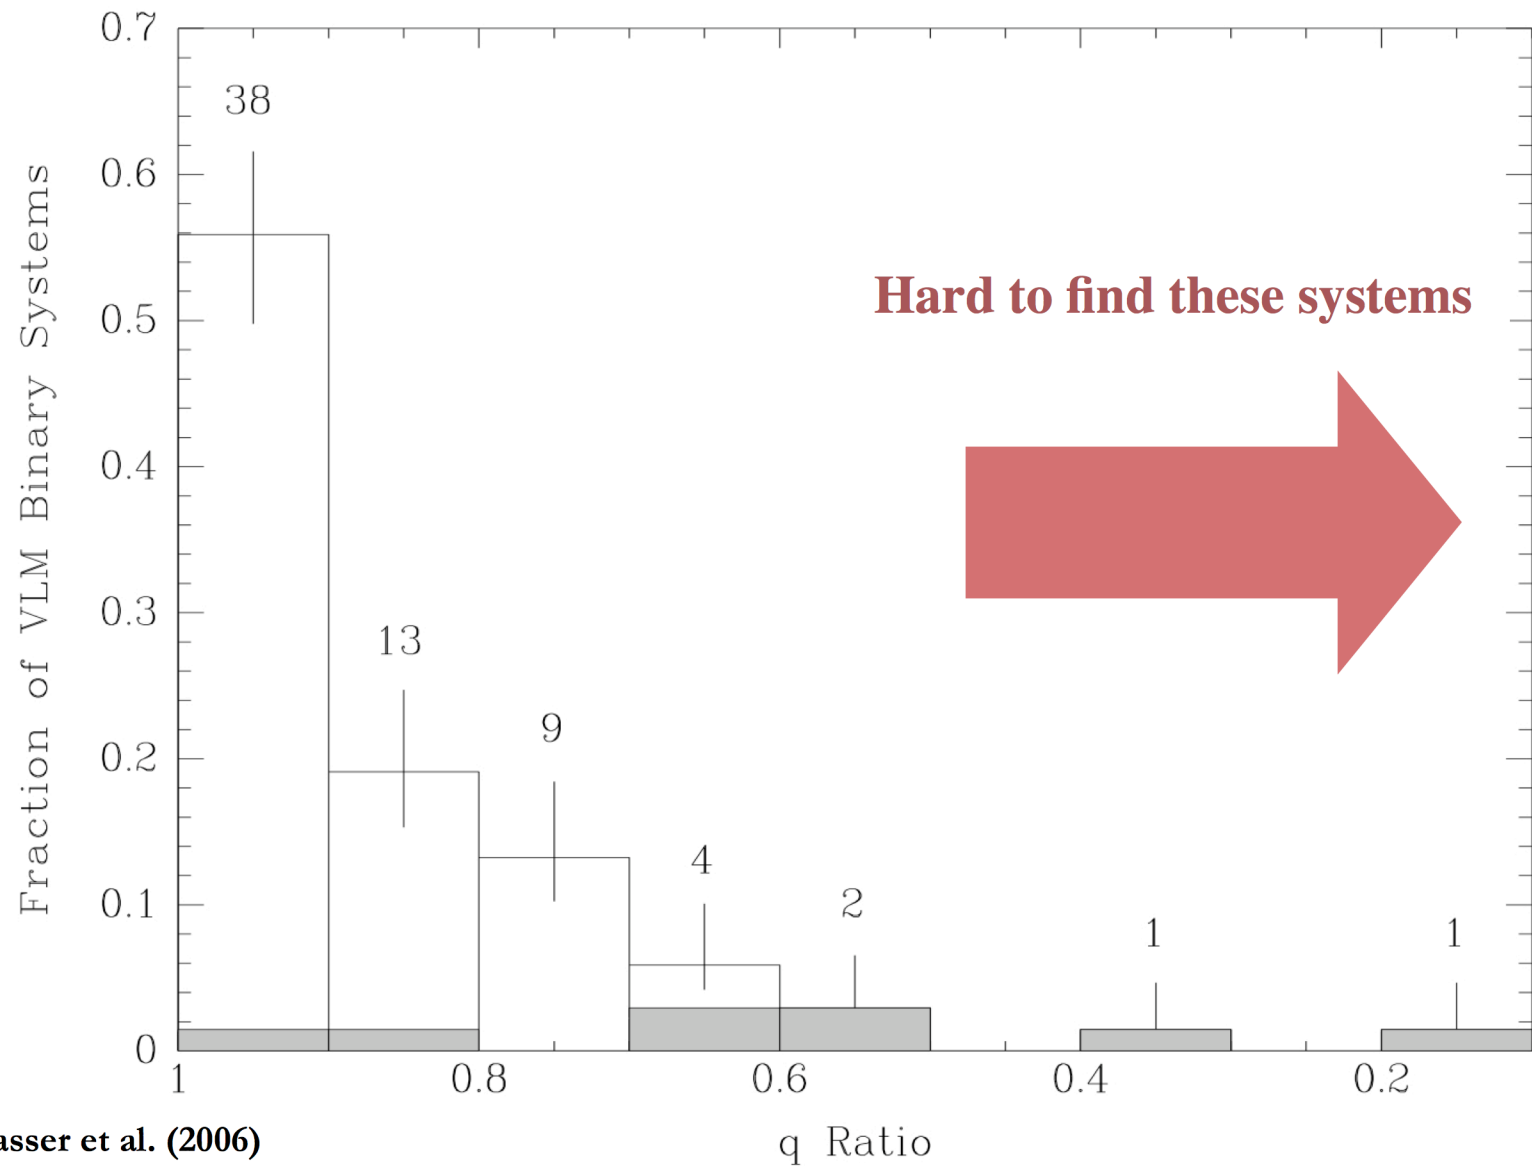

Burgasser et al. (2006)

# Mass Ratio Distribution

Burgasser et al. (2006)

# Mass Ratio Distribution

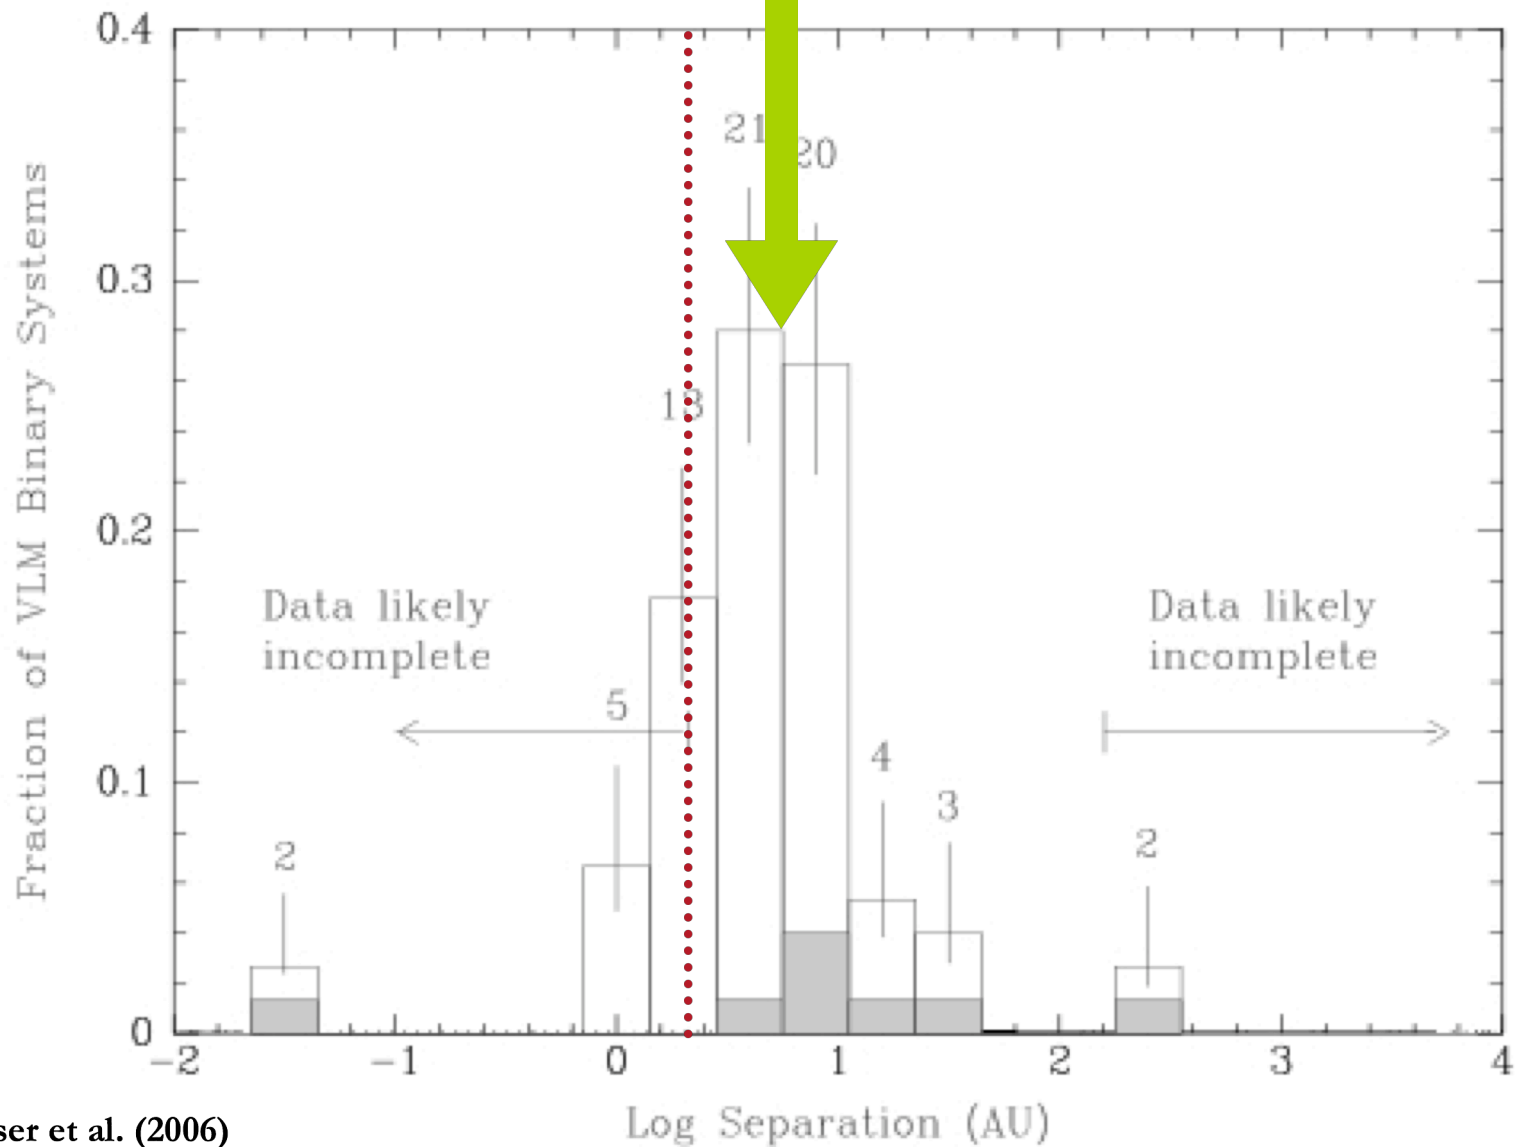

Burgasser et al. (2006)

# Separation Distribution

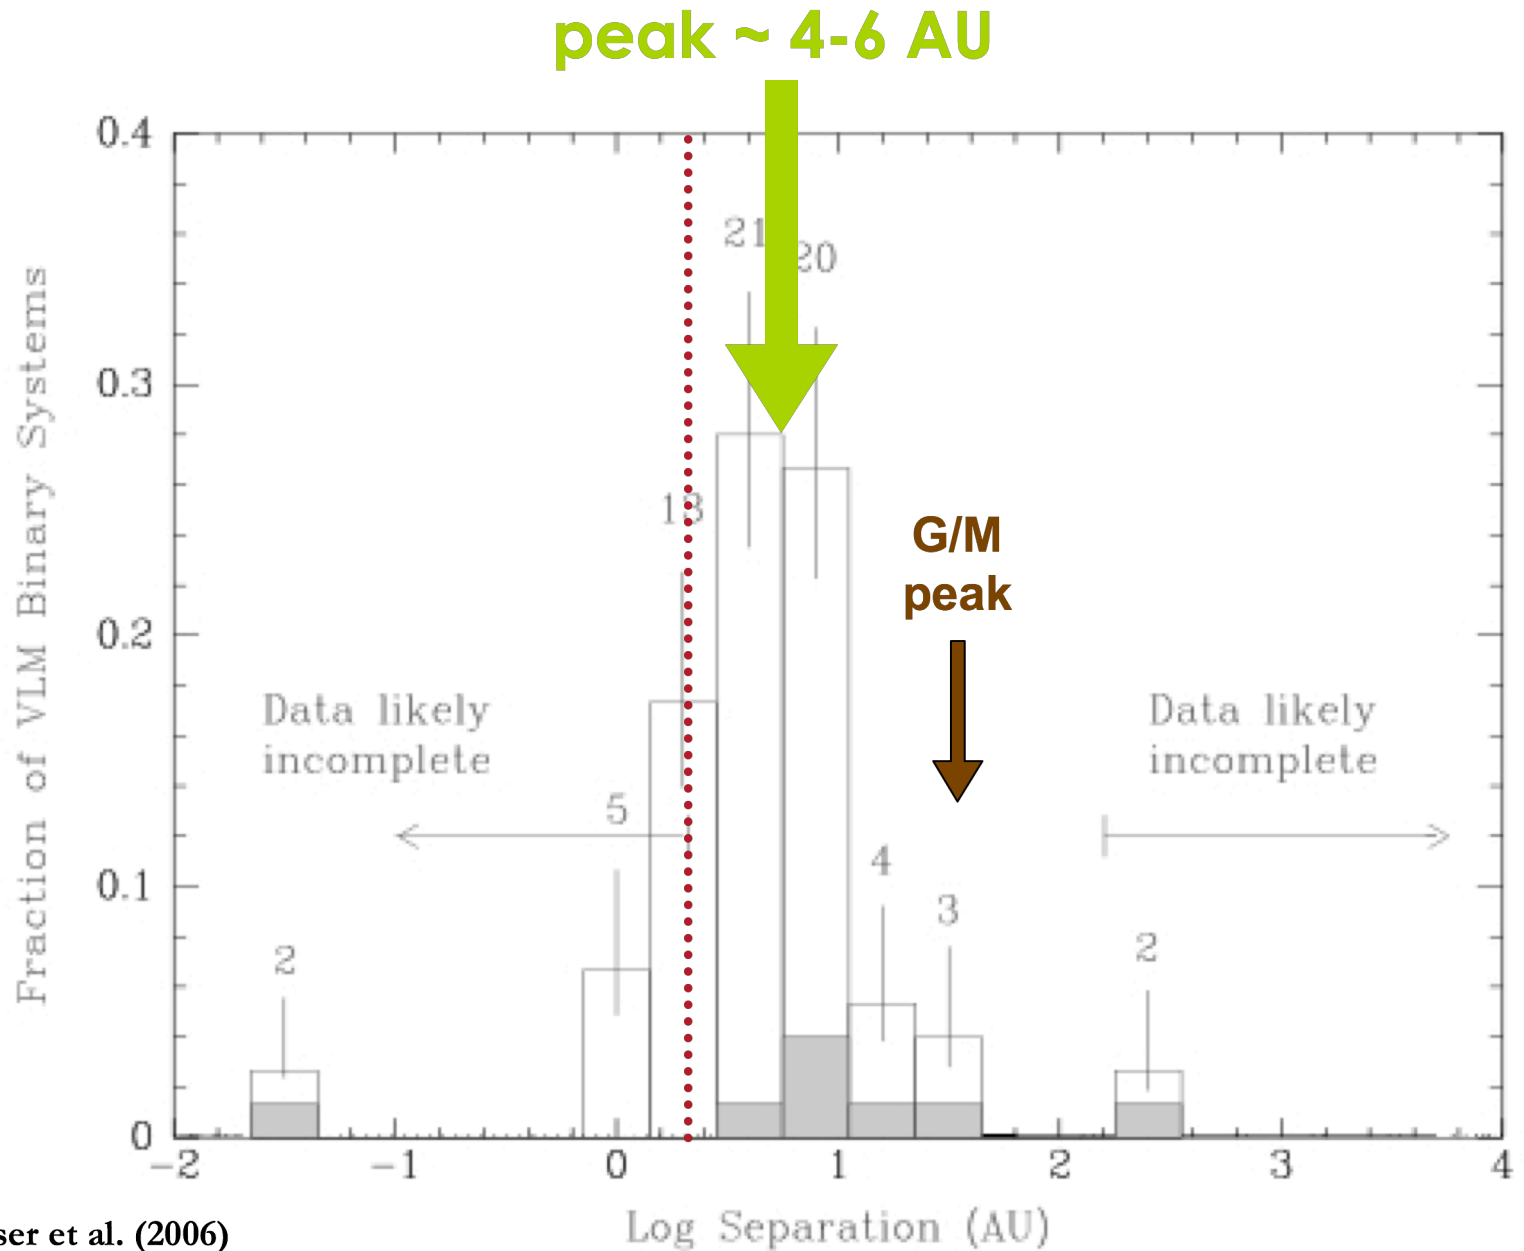

# Separation Distribution

peak ~ 4-6 AU

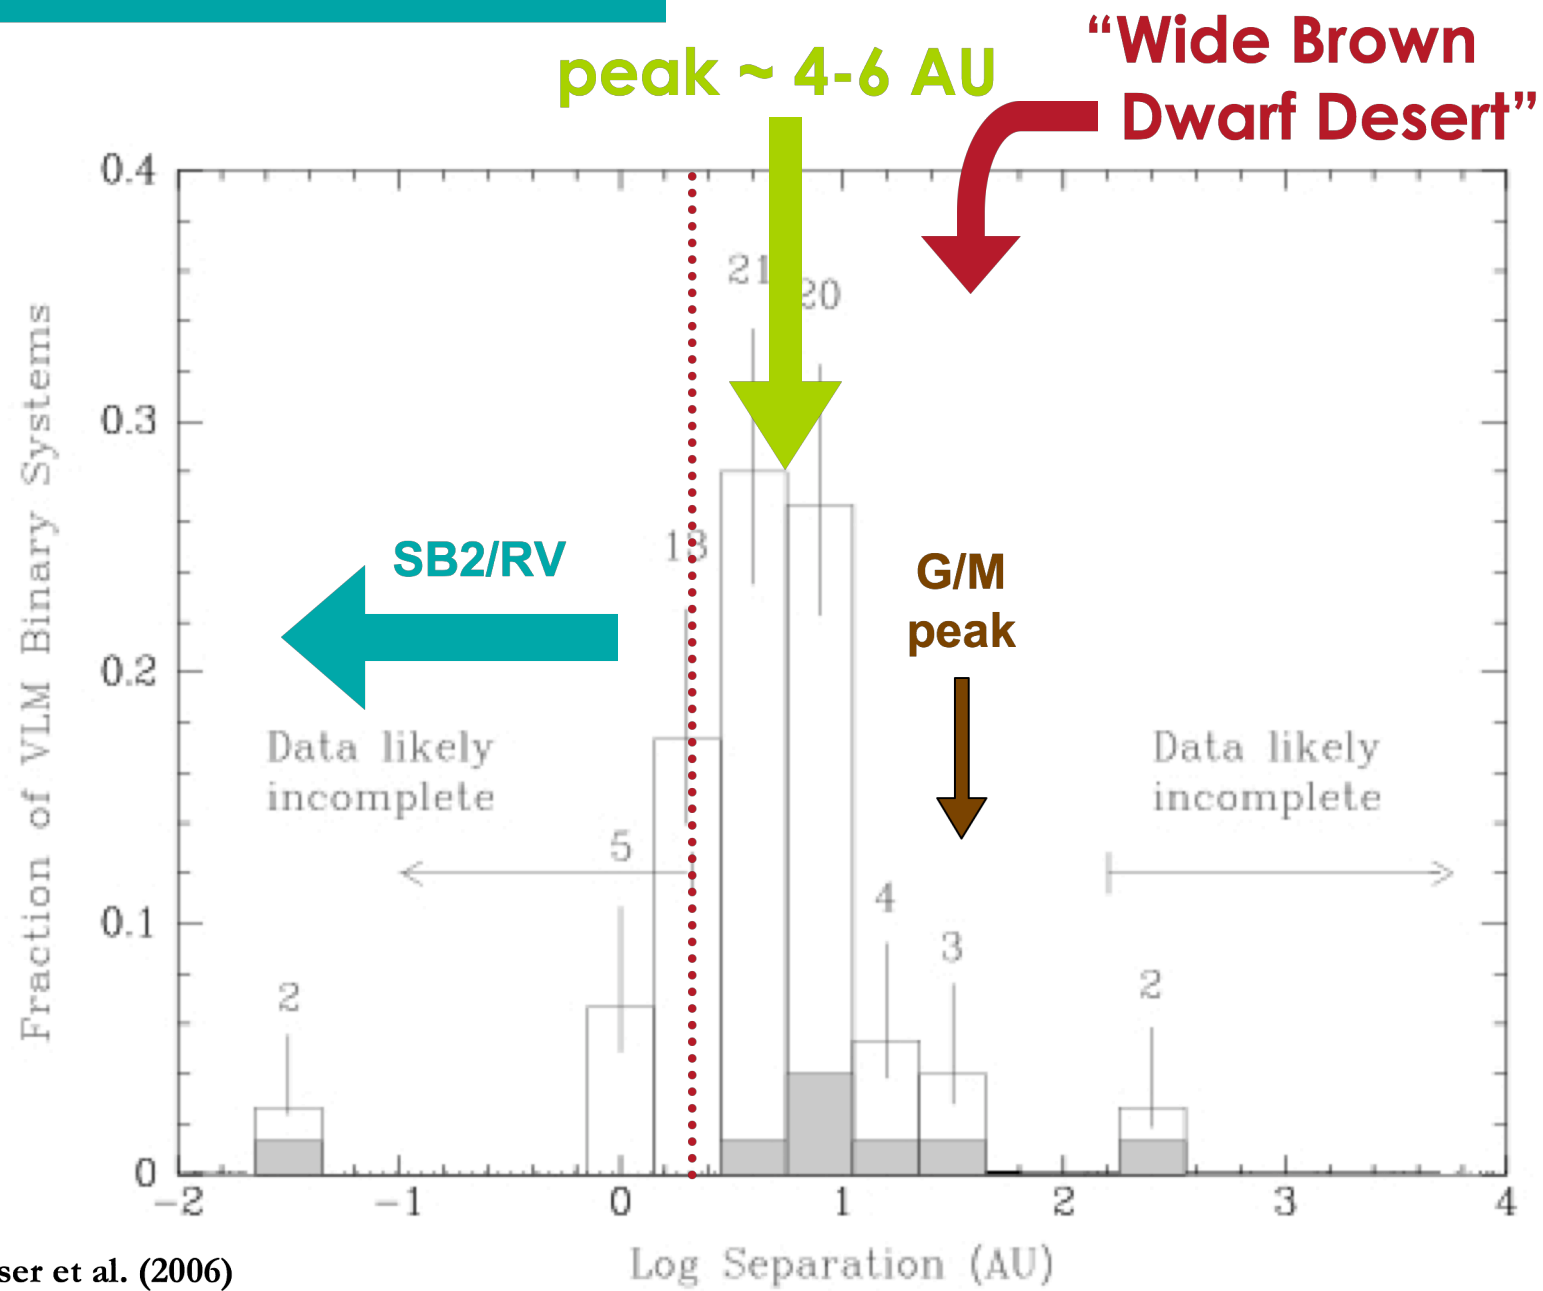

# Separation Distribution

# Separation Distribution

# Separation Distribution

Burgasser et al. (2006)

# The Binary Fraction

From imaging studies,  
apparent  $\epsilon_B \approx 20\%$

Selection effects:

- (1) Magnitude-limited samples (↓)
- (2) Resolution limits (↑)
- (3) Sensitivity limits (↑)

Correcting for (1)

⇒  $\epsilon_B \approx 10-15\%$

**Bouy et al. (2005)**

Reid et al. (1997); Bouy et al. (2005);  
White et al. (2006)

# Missing the close ones?

**Pinfield et al. (2003) & Chappelle et al. (2005):** unresolved overluminous sources in young clusters suggest  $\epsilon_B = 30-60\%$

**Maxted & Jeffries (2005):** analysis of early spectroscopic binary results indicates  $\epsilon_b = 17-30\%$  for  $a < 2.6$  AU  $\Rightarrow \epsilon_B = 32-45\%$  for all VLM binaries

**Burgasser (2007):** overluminous (unresolved) L/T transition objects suggests  $\epsilon_B = 24-53\%$  for brown dwarfs.

# The Binary Fraction

The VLM/BD multiple fraction may be much higher than currently stated if there are a large number of spectroscopic binary systems

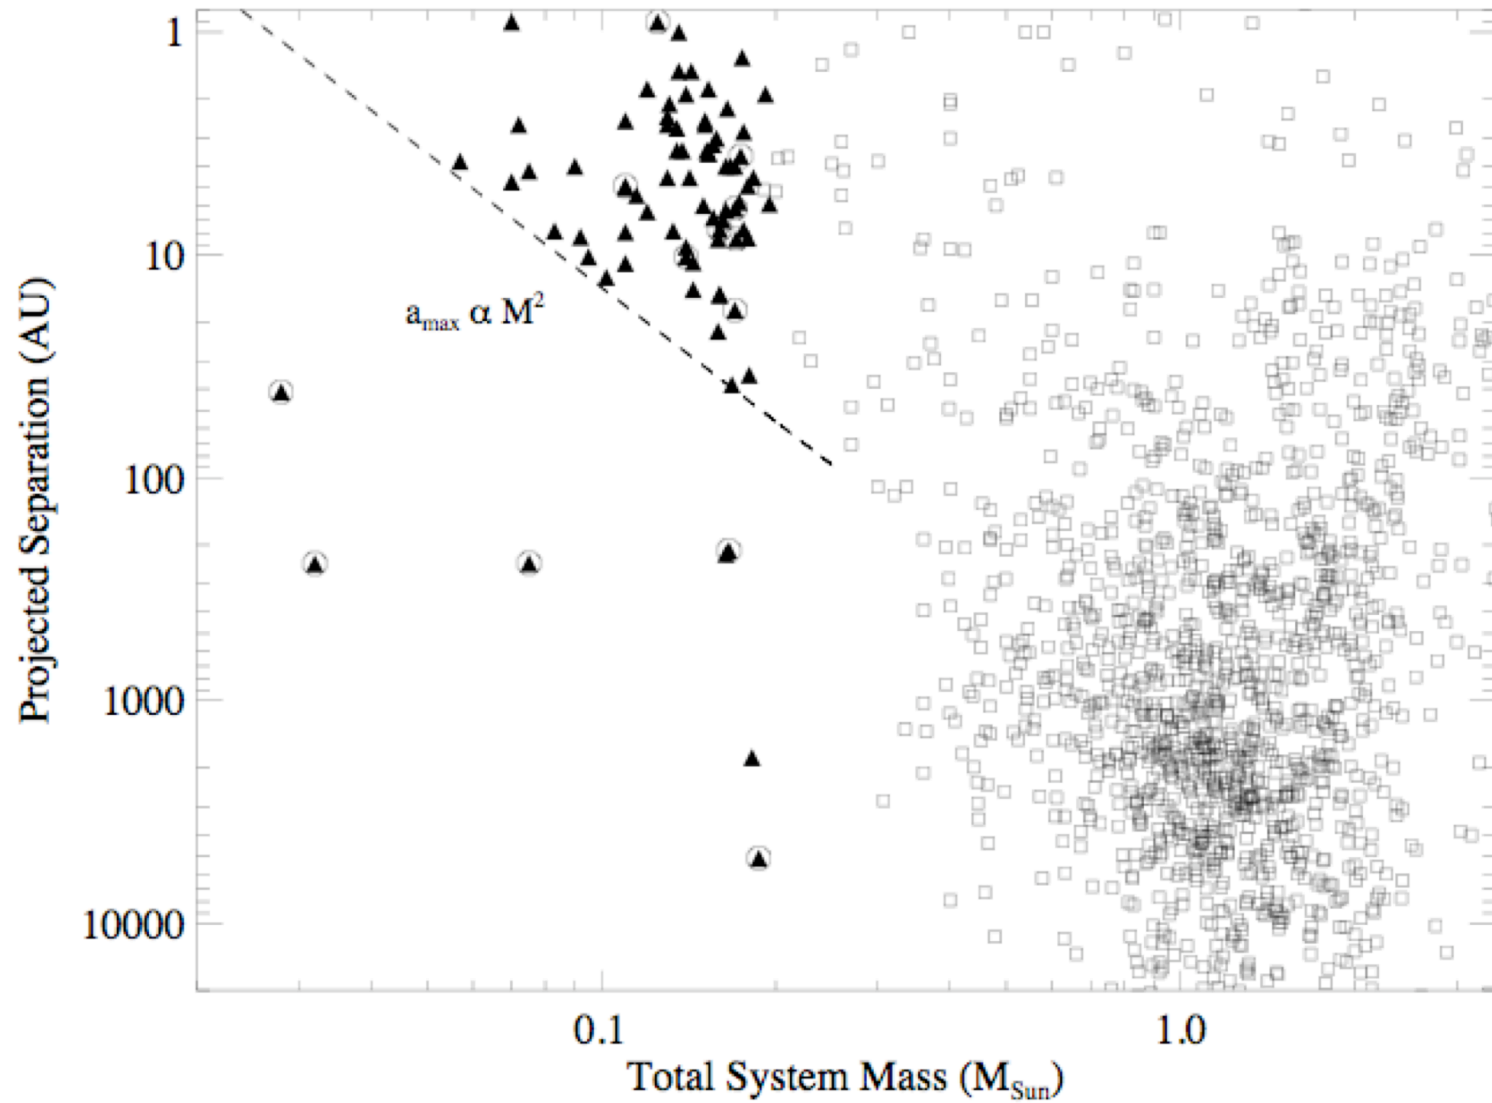

Are most VLM stars and BDs in multiple systems?

Bouy et al. (2005)

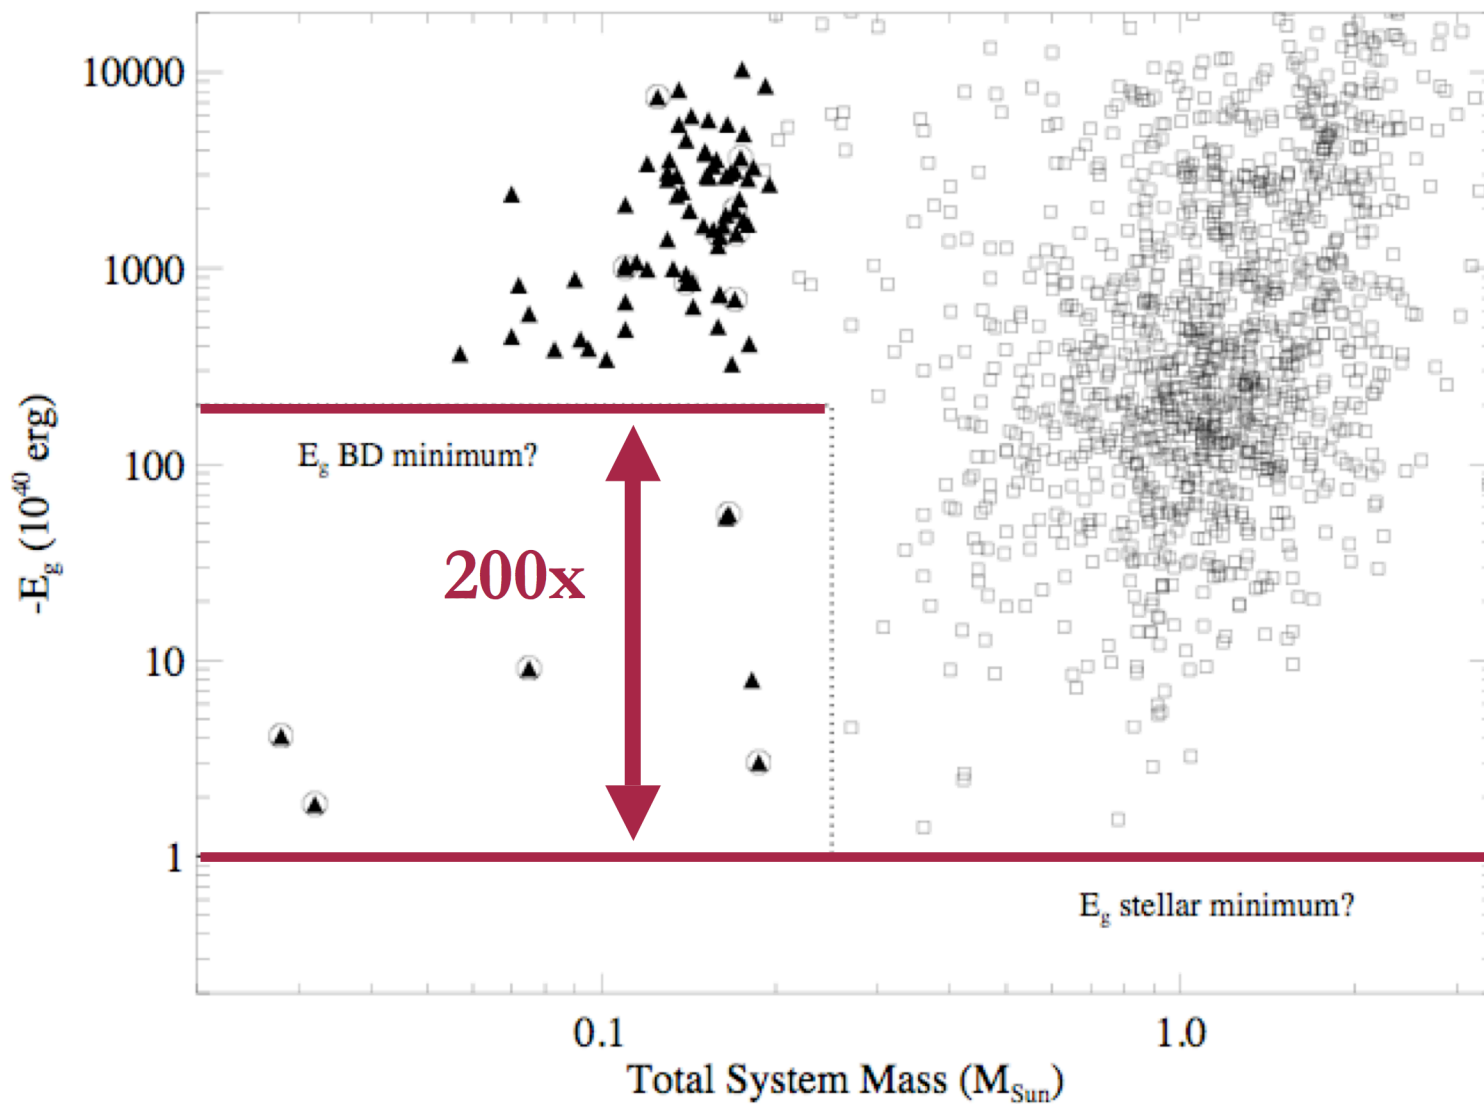

# Mass vs. Separation

Circles sources are younger than 10 Myr

# Mass vs. Binding Energy

Circles sources are younger than 10 Myr

# Common Outliers

- **2MASS 1207-3932AB** (42 AU): member of  $\approx 8$  Myr low density TW Hydrae association, still accreting (Chauvin et al. 2004, 2005)
- **2MASS 1101-7732AB** (242 AU): member of  $\approx 2$  Myr Chameleon I low density association (Luhman 2004)
- **Oph 11AB & 16AB** (243 & 212 AU): members of  $\approx 5$  Myr low density  $\rho$  Ophiuchus cloud complex (Allers 2005; Jayawardhana & Ivanov 2006; Close et al. 2006)
- **2MASS 0126-5022AB** (5100 AU!): probable member of  $\approx 8$  Myr low density TW Hydrae association (Artigau et al. 2007)
- **\*DENIS 0551-4434AB** (220 AU): old field M9/L0 pair (no Li I absorption) at 100 pc  $\Rightarrow$  very rare? (Billeres et al. 2005)

# How do formation models compare?

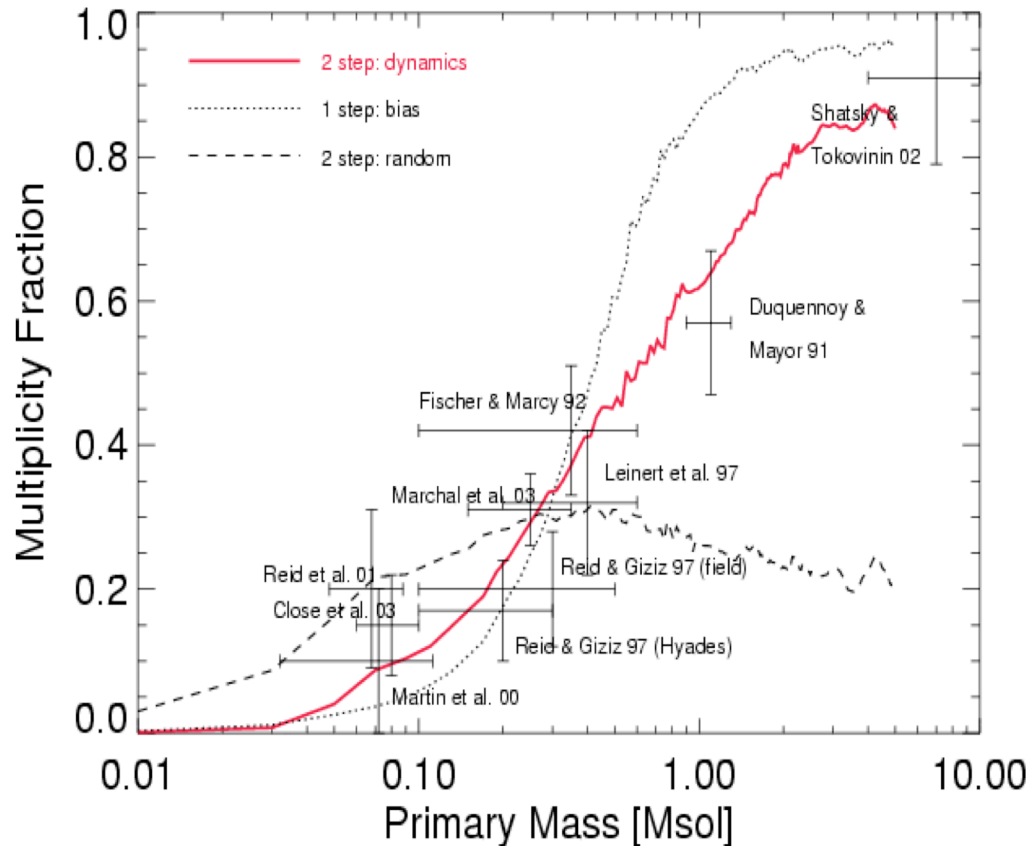

**SPH simulations** (gas  $\rightarrow$  stars) predict low VLM binary fractions ( $< 5\%$  to  $8\%$ ) and wider binaries for high density clouds  $\Rightarrow$  **not in line with observations.**

Limitations of sink particle size/Newtonian softening?

Bate et al. (2002)

# How do formation models compare?

Sterzik & Durison (2003)

**N-body simulations**  
(dynamics of small groups): reproduce decrease of binary fraction with mass, median separation  $\approx 3$  AU, few very close systems  $\Rightarrow$  **better match to data (perhaps)**

# Mass Measurements

Several systems have now been monitored for spectroscopic and/or astrometric orbital motion

Resulting mass measurements provide first real empirical tests of theoretical evolutionary models

**GJ 569Bab:**

Martin et al. 2000; Lane et al. 2001; Zapatero Osorio et al. 2004

**2MASS 0746+2000AB**  
Bouy et al. 2004

**2MASS 0535-0546AB**  
Stassun et al. 2006

# Observations v. Theory

Zapatero Osorio et al. (2004) for GJ 564Bab

Results for young systems GJ 564Bab (Zapatero Osorio et al. 2004) and 2MASS 0535-0546AB (Stassun et al. 2006) suggest **predicted substellar radii that may be too small at young ages.**

# 2MASS 0535-0546AB: Only Eclipsing Brown Dwarf Binary

Young ( $\approx 1$  Myr) system,  
masses  $0.05$  &  $0.03 M_{\odot}$ ,  
 $P = 9.8$  days

Unexplained  
temperature reversal -  
indicative of magnetic  
effects? Accretion?

Stassun et al. (2006)

# 2MASS 1207-3932AB: Accreting Brown Dwarf + “Planet”?

Chauvin et al. (2004)

M8 + L:: identified by adaptive optics, member of  $\approx 8$  Myr TW Hydrae association ( $d \sim 50$  pc)

Primary exhibits optical & X-ray accretion and IR excess

Secondary  $M \approx 3-8 M_{\text{Jupiter}}$   
(model-dependent)

Gizis (2002); Jayawardhana et al. (2003); Mohanty et al. (2003,2005,2007); Chauvin et al. (2004, 2005); Sterzik et al. (2004); Gizis et al. (2004; 2005); Mamjek (2005); Scholz et al. (2005, 2006); Song et al. (2006)

# Binary Lithium Test

Detection/absence of the 6708 Å Li I line in the spectrum of either component of a late-type M or L dwarf can provide constraints for both components, assuming coevality (Liu & Leggett 2005)

no Li detected

Test has yet to be done on resolved optical spectra!

Burgasser et al. (2006, in prep)

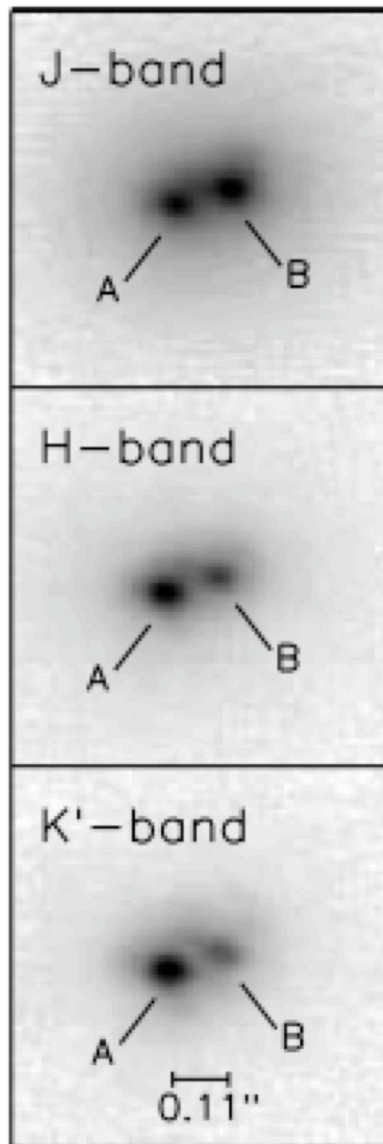

# Binaries and the L/T Transition

Transition between L and T spectral types poorly understood, but there are an **abundance of binaries** amongst them (~40% compared to ~20% observed) .

Binaries reveal brightening at 1.05 & 1.25  $\mu\text{m}$  between early- & mid-T possibly indicative of nonequilibrium loss of condensates (aka weather?)

SDSS 1534+1615AB:  
Liu et al. (2006)

SDSS 1021-0304AB: Burgasser et al. (2006)

# Brown dwarfs as companions

Grether & Lineweaver (2006)

Brown dwarfs are very rare as close companions ( $< 5$  AU) to stars: **“brown dwarf desert”**

At wider separations, brown dwarf companions are more common (2-15% for 30-1600 AU; Metchev 2005)

**GJ 569Bab:**  
 Martin et al. 2000; Lane et al. 2001; Zapatero Osorio et al. 2004

# Binaries as Companions

Many wide BD companions to nearby stars are themselves binary  $\Rightarrow$  excellent laboratories for testing models

Some indication that companion BDs are more frequently binary (Burgasser et al. 2005): a clue to formation?

**HD 130948Bab:**  
 Potter et al. (2002)

**Epsilon Indi Bab:**  
 McCaughrean et al. 2004

# Double planets

As of 2006, there are (officially) **no** double planets known! (Earth-Moon and Pluto-Charon were closest contenders)

Several multiple planet systems are known (including Solar System!)

# Planets in binary systems

> 23% of known EGPs reside in multiple systems (Raghavan et al. 2006), including one with a brown dwarf (HD 3651; Luhman et al. 2006; Mugrauer et al. 2006)

Simulations indicate that habitable terrestrial planets can be formed in systems with  $q_B > 10$  AU (Quintana et al. 2006)

Quintana et al. (2006)
