

## Questions

- Q: Which stays airborne longer: a bullet dropped from shoulder-height, or a bullet fired horizontally from rifle at 700 m/s?
- Q: An athlete { throws javelin } . How does  
{ dives off cliff } initial speed and direction affect (i) time of flight,  
(ii) distance traveled , (iii) angle of impact ?
- Q: Do we need to escape Earth's gravity to be  
(or feel) "weightless" ?

## Acceleration due to Gravity - Free Fall

(Physics at last!) Galileo found by experiment  
"All bodies fall at the same acceleration"  
(neglecting air friction)

- measured v, t to find accel. down slope

On earth, all bodies fall at constant

$$a = \leftarrow g = \leftarrow 9.81 \text{ m/s}^2$$

- objects pick up speed quickly!

e.g. 0 to 26.7 m/s (60 mph) in  $t = \frac{26.7-0}{9.81} = 2.7 \text{ s}$

covering a height  $h = \frac{1}{2}gt^2 = \frac{v^2}{2g} = 36.25 \text{ m}$

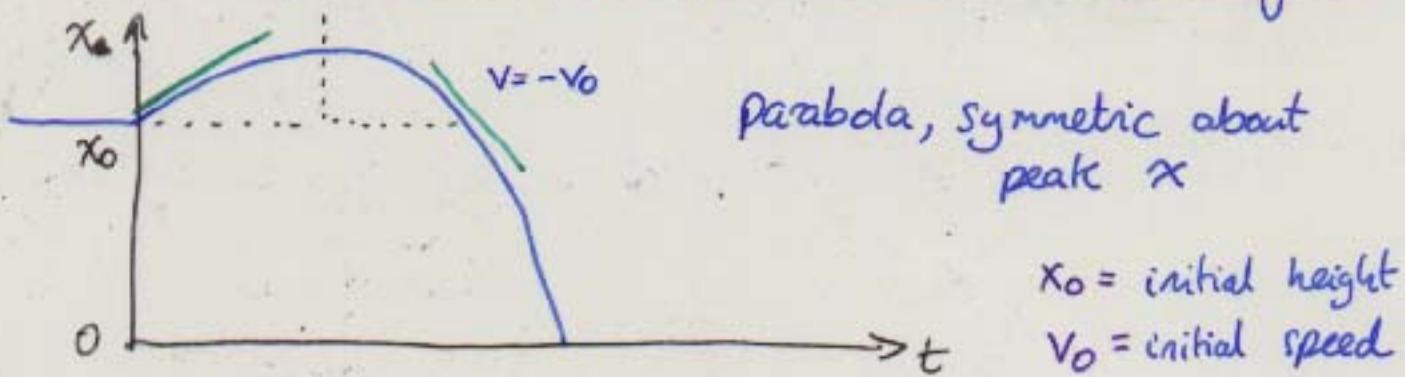

If initial speed  $v_0 \neq 0$  (upwards or downwards)

- just add or subtract from final speed

i.e.  $v = v_0 - gt$  : acceleration is the same

change in speed ( $v - v_0$ ) during flight is the same  
for same  $t$ .

## Free-fall motion of diver under constant "g":

Diver's height is a max. when  $\frac{dx}{dt} = 0 = v = v_0 - gt$

$$\text{i.e. } t(\text{max}) = \frac{v_0}{g}$$

$$\text{Max. height given by } v^2 = v_0^2 - 2g(x - x_0)_{\text{max}} = 0$$

$$\text{i.e. } x(\text{max}) = x_0 + \frac{v_0^2}{2g}$$

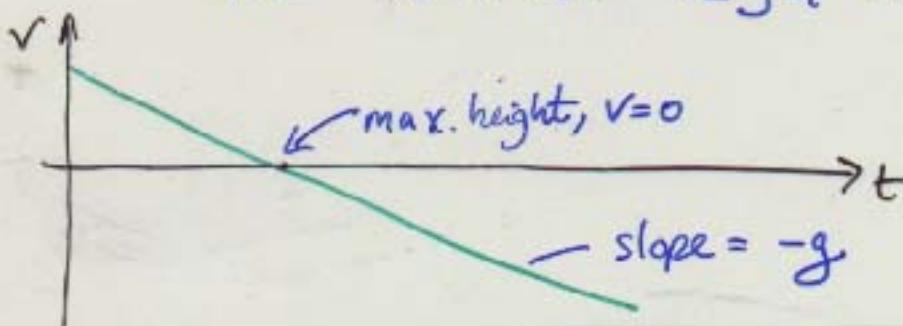

When diver hits pool ( $x=0$ ):

$$\text{Impact speed } v_i^2 = v_0^2 - 2g(-x_0) = \underline{\underline{v_0^2 + 2gx_0}}$$

$$\text{Time of flight } t_i = \frac{(v_i - v_0)}{a} = \underline{\underline{\frac{(v_i - v_0)}{-g}}}$$

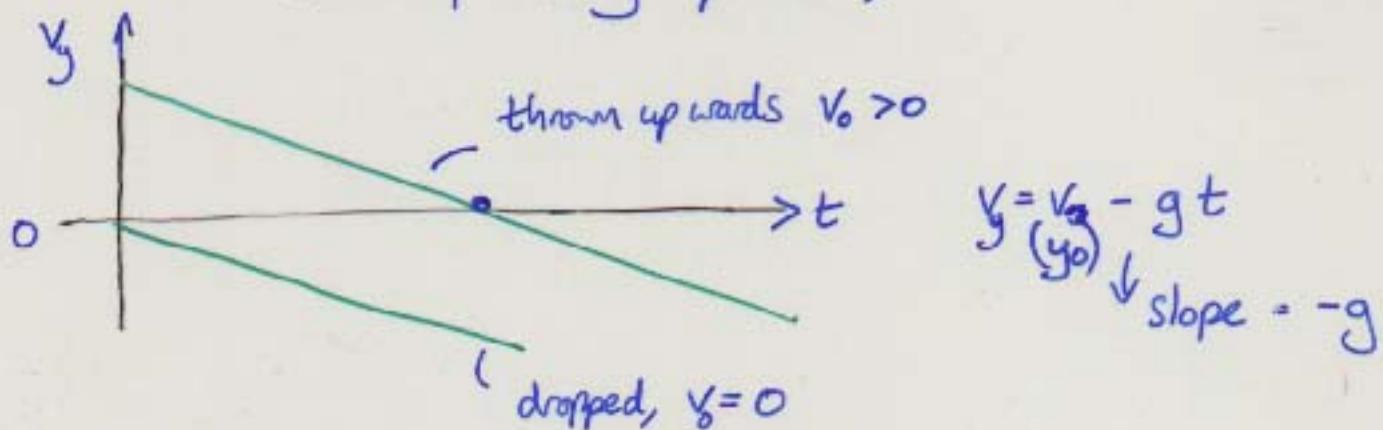

or given by solution of quadratic eqn:

$$x = x_0 + v_0 t - \frac{1}{2} g t_i^2 = 0$$

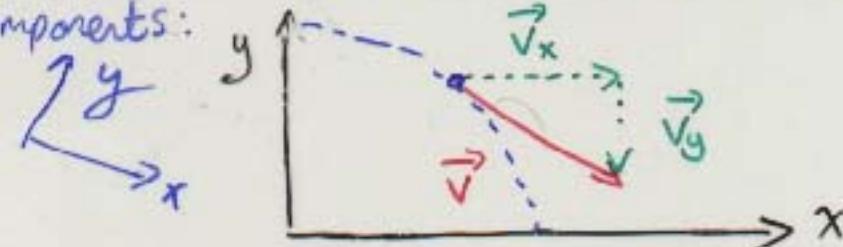

## Free-Fall in 2D : Projectiles

Projectile : thrown with initial velocity, moves under influence of gravity only : follows a trajectory in  $(x, y)$   
 "Free-fall" = accelerating downwards under gravity  
 (even if moving upwards)

Note: For now, neglect air friction : choose low speeds, dense objects (high mass, small size)

\* any point along 2D trajectory, can separate object's  $\vec{v}$  into components:

$$\vec{v} = \vec{v}_x + \vec{v}_y$$

choose  $\vec{g}$  to be ~~perp~~ to (-y) axis

Then:  $\vec{v} = v_x \hat{i} + v_y \hat{j}$  where  $v_x = \frac{dx}{dt}$  etc.

with  $\frac{d^2x}{dt^2} = 0$ ,  $\frac{d^2y}{dt^2} = -g$  since  $\vec{g} = -g \hat{j}$

i.e.  $v_x = \text{constant}, v_y = v_{yo} - gt$

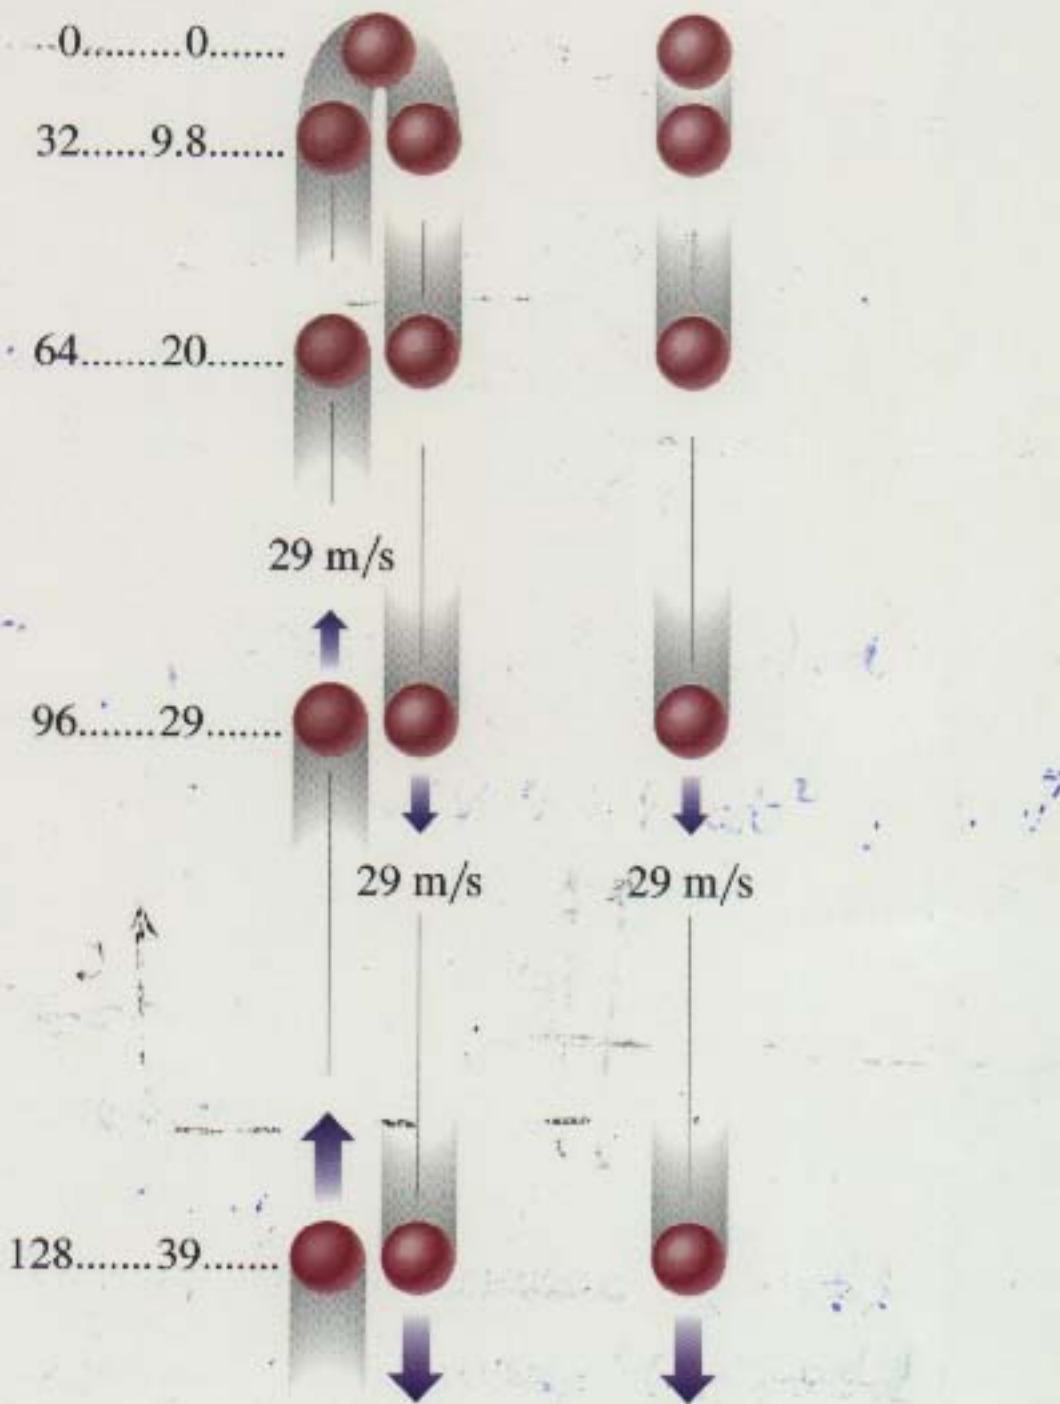

- motion in x direction unaffected by gravity!

Figure 3.11

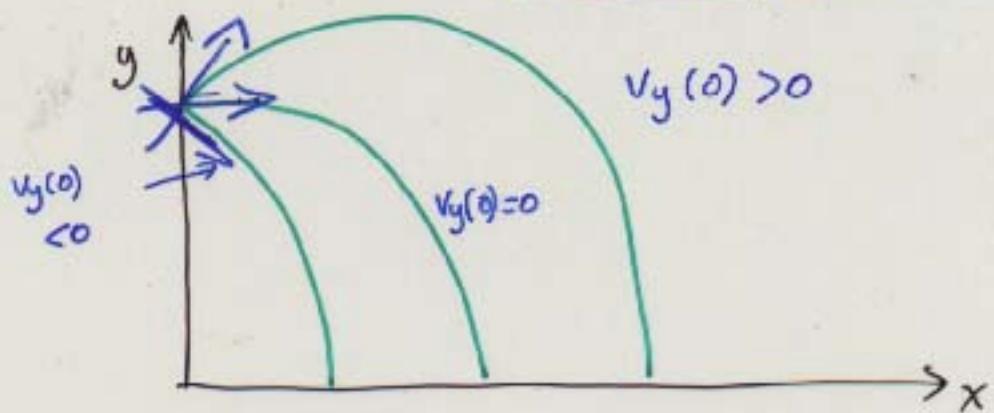

## Peak altitude of a moving ball

Speeds both upward and downward

(ft/s) (m/s)

## Parabolic paths

Shape of parabola (incl. max height, max. range)  
depends on magnitude and direction of  $\vec{v}_0$

Max. height is when  $v_y = \frac{dy}{dt} = \cancel{v_{y0}} - gt_{max} = 0$

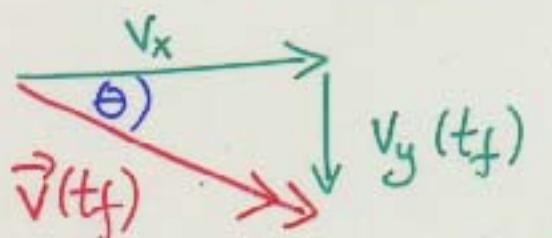

Time of flight  $t_f$  given by  $y(t_f) = y_0 - \cancel{v_{y0} t_f} - \frac{1}{2} g t_f^2 = 0$

Can then find distance traveled (range)  $x(t_f) = x_0 + v_x t_f$

Speed of impact, angle of impact found by

adding components:  $v_y(t_f) = v_{y0} - g t_f$

$$v_x(t_f) = v_x(0) (= v_0 \cos \theta)$$

Ex 3.16, 3.17

$$\text{Speed } v(t_f) = \sqrt{v_x^2 + v_y(t_f)^2}$$

$$\text{Angle } \theta = \tan^{-1} \frac{v_y(t_f)}{v_x(t_f)}$$

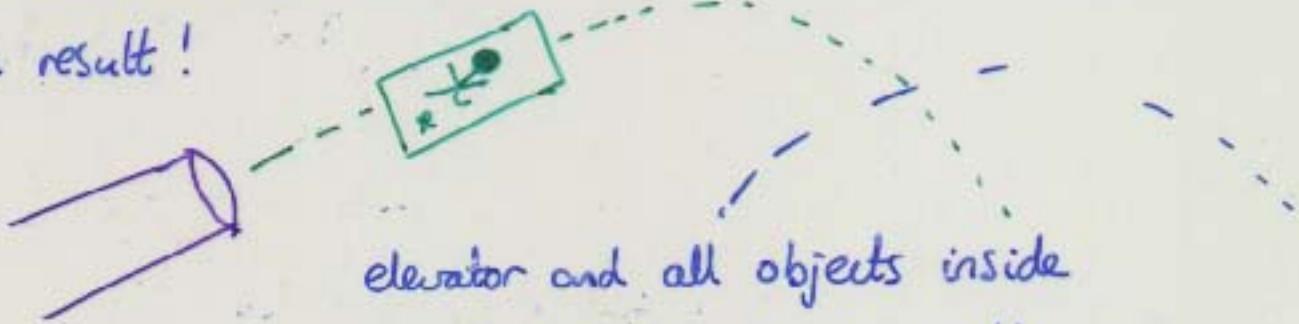

## Free-fall and "Weightlessness"

Since all freely-falling objects accelerate at  $g$

.... in falling elevator, no net accel. of objects  
(keys, internal organs) relative to each other.

So a being born in a falling elevator (or space-ship)  
will not know that gravity exists (if no windows)

We can also launch elevator upwards and still have  
same result!

elevator and all objects inside  
follow a free-fall parabolic path

- Used by NASA for astronaut training (and <sup>14</sup> Apollo 13 movie)
  - ~~Boeing 747~~ "Vomit Comet" flies in a parabolic climb/dive
  - ⇒ few minutes of "weightlessness"

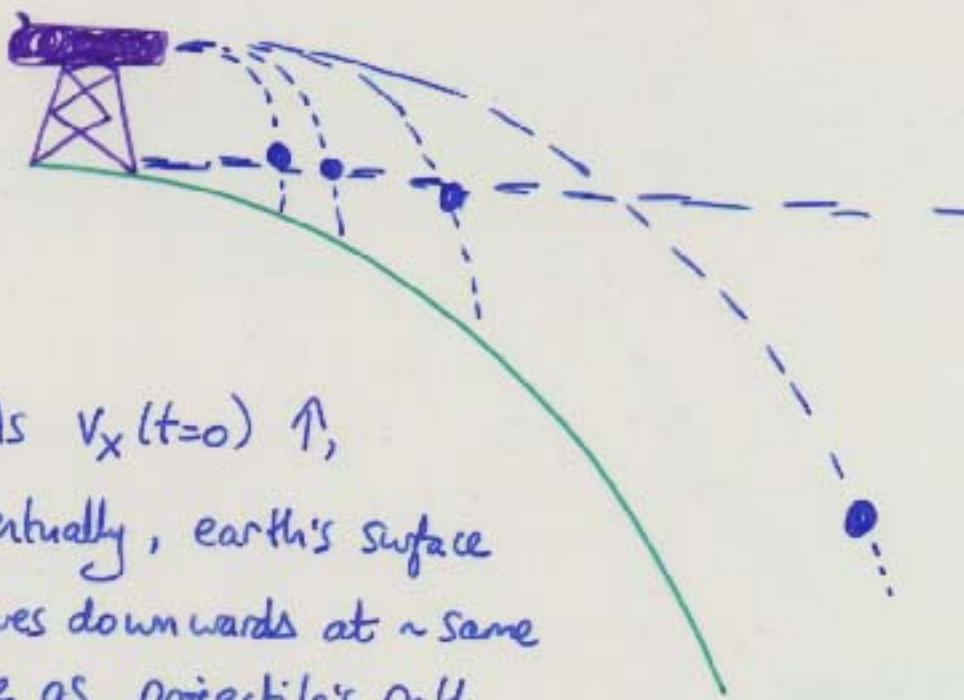

"Free-fall" ride at Magic Mountain

But height of ride  $y_0 = \frac{1}{2} g t_f^2$   
- expensive!

## Newton's Cannon - Weightlessness in Orbit

Newton theorized : build a powerful cannon on tall mountain. Fire horizontally , increasing initial speed:

As  $v_x(t=0) \uparrow$ ,  
eventually , earth's surface  
curves downwards at ~ same  
rate as projectile's path

→ projectile now in orbit !

∴ Shuttle crew in orbit are also in free-fall.  
Gravity is still strong close to earth but  
no net acceleration inside shuttle → "weightlessness".
